Local container stack

The root Compose file builds the API and web applications and starts PostgreSQL and MinIO. Development defaults are non-production values and can be overridden through a local `.env` file.

The MinIO initialization container creates the configured private bucket. Named volumes preserve PostgreSQL and object data between restarts; `docker compose down` leaves both volumes intact.

The pinned MinIO image is the final official container published by the archived community repository. It is restricted to local development; staging and production must use a maintained S3-compatible provider.
